# UNIVERSITY OF TORONTO Faculty of Arts and Science

#### **APRIL 2015 EXAMINATIONS**

# CSC 108 H1S

Instructor: Fairgrieve and Hagerman

Duration — 3 hours

**Examination Aids: None** 

You must earn at least 32 out of 80 marks (40%) on this final examination in order to pass the course. Otherwise, your final course grade will be no higher than 47%.

Student Number:					
Family Name(s):					
Given Name(s):					
	<del></del>				
Do not turn this page until you have received the sign					
In the meantime, please read the instructions below	carefully.				
	# 1:	/16			
al examination paper consists of 10 questions on 22 pages (including  a). When you receive the signal to start, please make sure that your  # 2:/ 4					
copy of the final examination is complete.	# 3:	/ 7			
• Comments and docstrings are not required except where indicated,	# 4:	/ 5			
although they may help us mark your answers.	# 5:	/ 7			
• You do not need to put import statements in your answers.	# 6:	/ 7			
• No error checking is required: assume all user input and all argument	# 7:	/ 5			
values are valid.	# 8:	/ 9			
<ul> <li>You may not use break or continue on this exam.</li> </ul>	# 9:	/ 8			
<ul> <li>If you use any space for rough work, indicate clearly what you want marked.</li> </ul>	# 10:	/12			
	TOTAL:	/80

# Question 1. [16 MARKS]

Part (a) [3 MARKS]

Consider this Python code:

L = [8, 12, 3]
X = L.sort()
Y = L[:]
L.extend([1])

print(X)
print(id(Y) == id(L))
print(L)

Write what this code prints when run, with one line per box. There may be more boxes than you need; leave unused boxes blank.

# Part (b) [2 MARKS]

Consider this Python code:

Write what this code prints when run, with one line per box. There may be more boxes than you need; leave unused boxes blank.

```
for i in range(2):
   for j in range(2):
     print('({0}, {1})'.format(i, j))
```

### Part (c) [2 MARKS]

Consider this Python code:

```
def find_bias(lst):
  """ (list of int) -> int
 bias = 0
 for num in 1st:
    if num % 2 == 0:
      return bias + 1
    else:
      return bias - 1
 return bias
```

Write what this code prints when run, with one line per box. There may be more boxes than you need; leave unused boxes blank.

 $my_list = [2, 4, 5, 6]$ print('The even/odd bias is:', find\_bias(my\_list))

# Part (d) [3 MARKS]

saved in the file words.py:

def func(word): print(\_\_name\_\_) word = word + 'Na' print ('0:', word) return word if \_\_name\_\_ == '\_\_main\_\_': word = 'Hey' print('1:', word) func(word) print('2:', word) word = func(word) + '!' print('3:', word)

Consider this Python code that has been Write what this code prints when words.py is run, with one line per box. There may be more boxes than you need; leave unused boxes blank.

#### Part (e) [2 MARKS]

Consider this Python code:

```
def f1(x, y):
    print('f1:', x, y)
    return x + y

def f2(x, y):
    print('f2:', x, y)
    return x * y

print(f1(f2(6, 5), f1(2, 4)))
```

Write what this code prints when run, with one line per box. There may be more boxes than you need; leave unused boxes blank.

•		

#### Part (f) [4 MARKS]

Consider this Python function:

```
def f(x):
    if x % 2 != 0:
        if x ** 2 <= 36:
            return 'Pow'
        else:
            return x // 3
    else:
        if x < 0 and abs(x) > 5:
            return False
        elif not x + 2 > 8:
            return x / 2
    return 'Zonk'
```

Four different calls to the function f() are given in the table below. Beside each call, write the value returned by f() and that value's type.

Call	Return Value	Return Type
f(2)		
f(13)		
f(-8)		
f(10)		

# Question 2. [4 MARKS]

Each of the following sets of Python statements will result in an error message being displayed when the code is run. Explain briefly the cause of each error in the table below.

Python statements	Explain briefly why an error message is displayed
<pre>month = 'April' date = 23 today = month + ' ' + date</pre>	
<pre>seasons = [' Winter ', ' Spring ',</pre>	
['2015', 'September'].extend(4)	
<pre>department = 'Computer Science' faculty = department[9:] faculty = faculty + [' 2015']</pre>	

 $\mathtt{CONT'D}.\;.\;.$ 

# Question 3. [7 MARKS]

Part (a) [3 MARKS] Consider this function header and docstring:

```
def cut_in_half(message):
    """ (str) -> list of str
```

Return a two-item list in which the first item is the first half of message and the second item is the second half of message. If the two halves of message are not the same length, the longer half should appear as the first item in the list.

In the table below, we have outlined two test cases for cut\_in\_half. Add three more test cases chosen to test the function thoroughly.

Test Case Description	message	Return Value
empty string	11	['','']
one character string	'p'	['p', '']

Part (b) [4 MARKS] Consider this function header and docstring:

```
def convocation_status(gpa):
    """ (float) -> str

Precondition: 0.0 <= gpa <= 4.0

Return 'with high distinction' if gpa is at least 3.5, 'with distiction' if gpa is at least 3.2 and less than 3.5, and 'regular' otherwise.</pre>
```

In the table below, we have outlined one test case for convocation\_status. Add four more test cases chosen to test the function thoroughly.

	Return Value
2.5	'regular'
	2.5

# Question 4. [5 MARKS]

Before completing your answer to this question, you may find it helpful to be reminded that the input() function returns a str containing the characters typed in by the program user. The trailing newline/return character ('\n') is stripped from the str before input() returns.

You may also find it helpful to consult the short Python function/method descriptions for S.isdigit() and int(x) that appear at the end of this exam paper.

Now consider the following function header, docstring and partial function body:

```
def get_valid_month():
    """ () -> int

    Return a valid month number input by user after (possibly repeated) prompting.

A valid month number is an int between 1 and 12 inclusive.

"""

prompt = 'Enter a valid month number: '
    error_message = 'Invalid input! Read the instructions and try again!'

# Use this statement as many times as needed for input:
    # month = input(prompt)

# Use this statement as many times as needed for output:
    # print(error_message)
```

Complete the body of the function according to its docstring description.

```
Question 5. [7 MARKS]
```

```
Part (a) [3 MARKS]
```

Consider this function header and docstring:

Write the body of the function according to its docstring description.

#### Part (b) [4 MARKS]

You have a very large file named twm\_times.txt that contains the completion times for runners in the 2014 Toronto Waterfront Marathon. Each line in the file contains a single time in the format of h:m:s. The first three lines in twm\_times.txt are:

```
2:8:15
2:8:36
2:8:41
```

Suppose that all runners with a completion time under 3:20:14 were to receive a special prize. To determine the number of runners who qualified for the prize, you ran the following statements in a Python shell:

```
>>> twm = open('twm_times.txt', 'r')
>>> print('Number of prize winners:', number_of_winners('3:20:14', twm))
>>> twm.close()
```

Write the body of the number\_of\_winners function according to its docstring description so that you will be able to easily determine the number of prize winners.

Return the number of lines in race\_results that contain a time that is below qualifying\_time.

CONT'D...

# Question 6. [7 MARKS]

On Assignment Two, you wrote code to implement the game Battleship. You may recall that in your code, you worked with a view\_board and a symbol\_board. Each board was a list of list of str, where each inner list represented one row of the board. We called each item in an inner list a cell. Cells were used to keep track of ship symbols, hits, misses, and so on.

In this question, you are to write a function that counts the number of hits and misses in each row of a board. Recall that we defined the named constants HIT and MISS using the statements:

```
HIT = 'X'
MISS = 'M'
```

[1, 2, 0]

Complete the following function according to its docstring description.

```
def count_hits_and_misses(board):
    """ (list of list of str) -> list of int

Precondition: board != [] and each list in board has len(board)

Return a list that contains the number of occurrences of the HIT or MISS symbol in each row of board.

>>> board = [['-','M','-'], ['X','M','-'], ['-','-','-']]
>>> count_hits_and_misses(board)
```

Page 10 of 22

Question 7. [5 MARKS]

Throughout this question, lists are to be sorted into ascending (increasing) order.

Part (a) [1 MARK] The list below is shown after each pass of a sorting algorithm.

[4, 9, 2, 1, 6, 5, 8] #initial list

Which sorting algorithm is being executed? (circle one)

- [1, 9, 2, 4, 6, 5, 8] # after one pass
- [1, 2, 9, 4, 6, 5, 8] # after two
- [1, 2, 4, 9, 6, 5, 8] # after three
- [1, 2, 4, 5, 6, 9, 8] # after four
- [1, 2, 4, 5, 6, 9, 8] # after five
- (a) bubble sort
- (b) selection sort
- (c) insertion sort

Part (b) [1 MARK] The list below is shown after each pass of a sorting algorithm.

[4, 9, 2, 1, 6, 5, 8] #initial list

Which sorting algorithm is being executed? (circle one)

- [4, 9, 2, 1, 6, 5, 8] # after one pass
- [4, 9, 2, 1, 6, 5, 8] # after two
- [2, 4, 9, 1, 6, 5, 8] # after three
- [1, 2, 4, 9, 6, 5, 8] # after four
- [1, 2, 4, 6, 9, 5, 8] # after five
- (a) bubble sort
- (b) selection sort
- (c) insertion sort

Part (c) [2 MARKS] List [7, 6, 3, 8, 1, 2, 0, 5] is being sorted using selection sort. Fill in the blanks to show the list after the next two passes.

After one pass:

[0, 6, 3, 8, 1, 2, 7, 5]

After two passes:

[0, 1, 3, 8, 6, 2, 7, 5]

After three passes:

After four passes:

Part (d) [1 MARK] Consider the following list: L = [1, 2, 3, 4, 5, 6]

Which algorithm would you expect to have a faster runtime? Circle one.

insertion sort

selection sort

they would require the same time

Page 11 of 22

Student #:

CONT'D...

# Question 8. [9 MARKS]

On Assignment Three, you wrote code to detect whether or not an input poem followed a particular rhyming scheme. You did this by first reading a Pronouncing Dictionary that contained lines like:

```
EXAMINATION IHO G Z AE2 M AHO N EY1 SH AHO N
```

and storing the lines in a Python dict of {str: list of str} that had key: value pairs like:

```
'EXAMINATION': ['IHO', 'G', 'Z', 'AE2', 'M', 'AHO', 'N', 'EY1', 'SH', 'AHO', 'N']
```

The helper function read\_pronunciation was called, and a Python dict named words\_to\_phonemes was used to store all of the words and associated phonemes that were in the Pronouncing Dictionary file dictionary.txt. After reading the Pronouncing Dictionary, you could get shell output like the following:

```
>>> words_to_phonemes['WILLIAM'] == ['W', 'IH1', 'L', 'Y', 'AHO', 'M']
True
```

To determine whether or not two words rhyme, you could make use of the helper function:

```
def last_phonemes(phoneme_list):
    """ (list of str) -> list of str
```

Return the last vowel phoneme and subsequent consonant phoneme(s) in phoneme\_list.

```
>>> last_phonemes(['AE1', 'B', 'S', 'IH0', 'N', 'TH'])
['IH0', 'N', 'TH']
>>> last_phonemes(['IH0', 'N'])
['IH0', 'N']
>>> last_phonemes(['B', 'S'])
[]
"""
```

On the assignment, we said that two different words rhyme if and only if their last vowel phonemes and all subsequent consonant phoneme(s) after the last vowel phonemes matched. Using this definition, you could get the shell results:

```
>>> last_phonemes(words_to_phonemes['COW']) == last_phonemes(words_to_phonemes['HOW'])
True
>>> last_phonemes(words_to_phonemes['COW']) == last_phonemes(words_to_phonemes['PIG'])
False
```

and conclude that 'COW' and 'HOW' rhyme, while 'COW' and 'PIG' do not rhyme.

Page 12 of 22

Part (a) [7 MARKS]

When writing poetry, it would be helpful to have a list of words that rhyme. Complete the following function according to its docstring description. Use the last\_phonemes function as a helper function.

```
def build_rhyming_dict(words_to_phonemes):
    """ (dict of {str: list of str}) -> dict of {str: list of str}
```

Return a dict where the keys are the same as the keys in word\_to\_phonemes and the value for each key is a list of all words that rhyme with the key.

Two words rhyme if and only if they are different and their last vowel phonemes and all subsequent consonant phoneme(s) after the last vowel phonemes match.

```
>>> words_to_phonemes = read_pronunciation(open('dictionary.txt'))
>>> words_to_rhyming_words = build_rhyming_dict(words_to_phonemes)
>>> words_to_rhyming_words['CRAIG']
['BAIG', 'BEGUE', 'FLAIG', 'HAGUE', 'HAIG', 'LAPHROAIG', 'MACIAG',
   'MCCAGUE', 'MCCAIG', 'MCKAIG', 'MCQUAIG', 'MCTAGUE',
   'NEST-EGG', "O'LAGUE", 'PLAGUE', 'RAGUE', 'SPRAGUE', 'VAGUE']
>>> # Notice that 'CRAIG' is not in the list of words that rhyme with 'CRAIG'
```

CONT'D...

Part (b) [2 MARKS] One instructor's solution to Part (a) had a runtime that is best described as being quadratic in the length of the words\_to\_phonemes Python dict. If it took 1 second for the build\_rhyming\_dict function to run for a words\_to\_phonemes dict containing 1000 words, roughly how long would you expect the build\_rhyming\_dict function to take when the words\_to\_phonemes dict was doubled in length to a size of 2000 words? Justify your response.

# Question 9. [8 MARKS]

Consider the following Python function. The docstring has been shortend to save space.

```
def bark_like_a_dog(L):
    """ (list of object) -> NoneType
    """
    for item in L:
        print('Woof!')
```

Each of the following sets of Python code operate on a list named L. You may assume that L refers to a list of objects and that len(L) is n. For each set of Python code, write a formula that expresses approximately how many times the word Woof! is printed. The formula may depend on n. In addition, circle whether the dependence on n is constant, linear, quadratic or something else.

	How many times is Woof! printed?	Dependence
Python code	(approximately)	on n
		(circle one)
		constant
bark_like_a_dog(L)		linear
		quadratic
		something else
i = 0		constant
while i < len(L):		linear
bark_like_a_dog(L[i:i+1])		quadratic
i = i + 1		something else
i = 0		constant
while i < len(L):		linear
bark_like_a_dog(L[i:])		quadratic
i = i + 1		something else
i = 0		constant
while not(i < len(L)):		linear
bark_like_a_dog(L)		quadratic
i = i + 1		something else

Page 14 of 22

# Question 10. [12 MARKS]

In this question you will develop two classes that are part of an alarm notification system. The class Timestamp creates an object that holds a time (hour, minute and second) and a message. The class AlarmSchedule holds a list of Timestamp objects.

Here is the header and docstring for class Timestamp.

```
class Timestamp:
    """ Time and message for a timestamp. """
Part (a) [2 MARKS]
Complete method __init__ for class Timestamp.
    def __init__(self, h, m, s, msg):
        """ (Timestamp, int, int, int, str) -> NoneType
        Precondition: 0 \le h \le 23 and 0 \le m \le 59 and 0 \le s \le 59
        Initialize the hour h, minute m, second s, and message msg associated
        with this Timestamp.
        >>> ts1 = Timestamp(14, 10, 42, 'Relax')
        >>> tsl.hour
        14
        >>> ts1.min
        10
        >>> ts1.sec
        42
        >>> ts1.msg
        'Relax'
        11 11 11
```

### Part (b) [2 MARKS]

In order to compare objects of type Timestamp, it is useful to be able to work with just the time (hour, minute and second) and not the message. Here is the header, type contract and description for a method time in class Timestamp. Write the body of the method.

```
def time(self):
    """ (Timestamp) -> str

Return a string representation of the time associated with this Timestamp.

>>> ts1 = Timestamp(14, 9, 1, 'Relax')
>>> ts1.time()
'14:9:1'
"""
```

### Part (c) [4 MARKS]

Follow the function design recipe to write an \_\_eq\_\_ method for class Timestamp. This method will give us a way to determine whether or not two Timestamp objects contain the same information. Consider two timestamps to be equal if and only if they have the same time (hour, minute and second) and the same message. (Your code may call helper functions/methods, but this is not required.)

Here is the header and docstring for class AlarmSchedule. In parts (d) and (e), you will write methods for class AlarmSchedule.

#### class AlarmSchedule:

""" Contains information about Timestamp objects in an alarm schedule. """

#### **Part** (d) [1 MARK]

Complete method \_\_init\_\_ for class AlarmSchedule.

Note: you will probably not need all of the space on this page.

```
def __init__(self):
    """ (AlarmSchedule) -> NoneType
    Initialize an AlarmSchedule with an empty list named schedule.
```

>>> alarms = AlarmSchedule()

>>> alarms.schedule

[]

11 11 11

### Part (e) [3 MARKS]

Complete method add in class AlarmSchedule.

```
def add(self, tstamp):
    """ (AlarmSchedule, Timestamp) -> NoneType

Modify schedule to add Timestamp tstamp, provided there is not an existing Timestamp with the same time.

>>> alarms = AlarmSchedule()
>>> alarms.add(Timestamp(14, 10, 42, 'Relax'))
>>> alarms.add(Timestamp(14, 23, 39, 'Sigh'))
>>> alarms.add(Timestamp(14, 10, 42, 'Burp'))
>>> alarms.schedule[0].msg
'Relax'
>>> alarms.schedule[1].msg
'Sigh'
>>> len(alarms.schedule)
2
```

Page 18 of 22 Cont'd...

[Use the space below for rough work. This page will **not** be marked, unless you clearly indicate the part of your work that you want us to mark.]

Page 19 of 22

Student #:

#### Short Python function/method descriptions:

```
__builtins__:
 abs(x) -> number
   Return the absolute value of x.
 input([prompt]) -> str
   Read a string from standard input. The trailing newline is stripped. The prompt string,
    if given, is printed without a trailing newline before reading.
 int(x) \rightarrow int
   Convert x to an integer, if possible. A floating point argument will be truncated
    towards zero.
 len(x) \rightarrow int
   Return the length of the list, tuple, dict, or string x.
 max(iterable) -> object
 max(a, b, c, ...) \rightarrow object
    With a single iterable argument, return its largest item.
    With two or more arguments, return the largest argument.
 min(iterable) -> object
 min(a, b, c, ...) \rightarrow object
     With a single iterable argument, return its smallest item.
      With two or more arguments, return the smallest argument.
  open(name[, mode]) -> file open for reading, writing, or appending
    Open a file. Legal modes are "r" (read), "w" (write), and "a" (append).
 print(value, ..., sep=' ', end='\n') -> NoneType
    Prints the values. Optional keyword arguments:
    sep: string inserted between values, default a space.
    end: string appended after the last value, default a newline.
  range([start], stop, [step]) -> list-like-object of int
    Return the integers starting with start and ending with stop - 1 with step specifying
    the amount to increment (or decrement).
    If start is not specified, the list starts at 0. If step is not specified,
    the values are incremented by 1.
dict:
  D[k] --> object
    Produce the value associated with the key k in D.
  del D[k]
    Remove D[k] from D.
  k in d --> bool
    Produce True if k is a key in D and False otherwise.
  D.get(k) -> object
    Return D[k] if k in D, otherwise return None.
  D.keys() -> list-like-object of object
    Return the keys of D.
  D.values() -> list-like-object of object
    Return the values associated with the keys of D.
  D.items() -> list-like-object of tuple of (object, object)
    Return the (key, value) pairs of D, as 2-tuples.
```

Page 20 of 22 Cont'd...

```
file open for reading:
  F.close() -> NoneType
    Close the file.
  F.read() -> str
    Read until EOF (End Of File) is reached, and return as a string.
  F.readline() -> str
    Read and return the next line from the file, as a string. Retain newline.
    Return an empty string at EOF (End Of File).
  F.readlines() -> list of str
    Return a list of the lines from the file. Each string ends in a newline.
file open for writing:
  F.close() -> NoneType
    Close the file.
  F.write(x) -> int
    Write the string x to file F and return the number of characters written.
list:
  x in L --> bool
    Produce True if x is in L and False otherwise.
  L.append(x) -> NoneType
    Append x to the end of the list L.
  L.extend(iterable) -> NoneType
    Extend list L by appending elements from the iterable. Strings and lists are
    iterables whose elements are characters and list items respectively.
  L.index(value) -> int
    Return the lowest index of value in L.
  L.insert(index, x) -> NoneType
    Insert x at position index.
  L.pop() -> object
    Remove and return the last item from L.
  L.remove(value) -> NoneType
    Remove the first occurrence of value from L.
 L.reverse() -> NoneType
    Reverse *IN PLACE*.
 L.sort() -> NoneType
    Sort the list in ascending order *IN PLACE*.
str:
 x in s --> bool
    Produce True if and only if x is in s.
  str(x) -> str
    Convert an object into its string representation, if possible.
 S.count(sub[, start[, end]]) -> int
    Return the number of non-overlapping occurrences of substring sub in
    string S[start:end]. Optional arguments start and end are interpreted
    as in slice notation.
 S.find(sub[, i]) -> int
    Return the lowest index in S (starting at S[i], if i is given) where the
    string sub is found or -1 if sub does not occur in S.
 S.index(sub) -> int
    Like find but raises an exception if sub does not occur in S.
```

S.isalpha() -> bool

Return True if and only if all characters in S are alphabetic and there is at least one character in S.

S.isdigit() -> bool

Return True if all characters in S are digits and there is at least one character in S, and False otherwise.

S.islower() -> bool

Return True if and only if all cased characters in S are lowercase and there is at least one cased character in S.

S.isupper() -> bool

Return True if and only if all cased characters in S are uppercase and there is at least one cased character in S.

S.lower() -> str

Return a copy of the string S converted to lowercase.

S.lstrip([chars]) -> str

Return a copy of the string S with leading whitespace removed.

If chars is given and not None, remove characters in chars instead.

S.replace(old, new) -> str

Return a copy of string S with all occurrences of the string old replaced with the string new.

S.rstrip([chars]) -> str

Return a copy of the string S with trailing whitespace removed.

If chars is given and not None, remove characters in chars instead.

S.split([sep]) -> list of str

Return a list of the words in S, using string sep as the separator and any whitespace string if sep is not specified.

S.strip([chars]) -> str

Return a copy of S with leading and trailing whitespace removed.

If chars is given and not None, remove characters in chars instead.

S.upper() -> str
